

Summary Report: What Factors Increase the Severity of an Accident?

This report looks at how different road features affect the seriousness of traffic accidents. By comparing the percentage of severe and minor accidents at various locations, we can find areas with a higher risk of serious crashes. The data shows that some road features are linked to more severe accidents, while others mostly have minor ones.

One of the biggest findings is that **Junctions and Traffic Signals** have a high number of severe accidents. **Junctions** account for **40.7% of severe accidents**, which is much higher than the **14.0% of minor accidents** that happen there. **Traffic Signals** are involved in **37.3% of severe accidents** and **28.8% of minor accidents**, showing that serious crashes are more common at these locations.

On the other hand, **Crossings** show a different trend. While they are a common accident location, they have more minor accidents (**28.4%**) than severe ones (**16.3%**). This suggests that although accidents happen often at crossings, they tend to be less serious. Similarly, **Stop Signs** have more minor accidents (**6.9%**) compared to severe ones (**3.4%**), possibly due to small crashes like rear-end collisions.

Other road features like **Stations, Railways, Amenities, Give Way Signs, No Exit Roads, and Traffic Calming Areas** have far fewer accidents. In most cases, there are slightly more minor accidents than severe ones, but the overall numbers are very low. Some features, like **Bumps, Roundabouts, and Turning Loops**, have almost no accidents in this data.

These insights are especially useful for **emergency response teams**. Since **Junctions and Traffic Signals** are the most dangerous spots for severe accidents, emergency teams can plan better responses. This could mean placing resources closer to these locations, using specialized equipment for serious injuries, or improving road designs to lower risks.

In conclusion, this analysis shows a clear connection between road features and accident severity. **Junctions and Traffic Signals** are high-risk areas for serious crashes and need special attention from emergency response teams. By focusing on these patterns, emergency services can improve their response times and strategies, ultimately helping save more lives.
