

Summary Report: Where Do Road Accidents Happen?

Premiga Pengtap · Data: US Accidents (Kaggle, March 2023), 2016–2023

This report looks at which road features are recorded most often at the sites of US traffic accidents. Traffic signals, crossings and junctions together make up about 80% of all road-feature flags, so they are where most accidents cluster.

Key findings

- **Traffic Signals (35.4%), Crossings (27.0%) and Junctions (17.7%)** account for most flags. These are conflict points where drivers, pedestrians and turning vehicles meet.
- **Stop signs (6.6%) and Stations (6.2%)** come next. Every other feature is 3% or less.
- Roundabouts, bumps and turning loops appear very rarely. This is partly because there are far fewer of them on US roads, so the data alone cannot show that they are safer.

Suggestions for planners

- Focus safety reviews on signalised intersections, crossings and junctions, where the volume of accidents is highest.
- Improve visibility and lighting at pedestrian crossings, and review signal timing to reduce red-light running.
- Where a junction has repeated accidents, consider simpler layouts or a roundabout, and test the effect with before/after data.

Limitations

Percentages are shares of road-feature flags, not accident rates. One accident can have several flags, and accidents with no flag are not counted. Without data on how many of each feature exist and how much traffic uses them, this analysis shows *where accidents are recorded*, not *which features are riskier*. Joining road-network and traffic-volume data would allow true risk rates.
